Plugin Architectures in Haskell

An Overview over the ecosystem

Sebastian Graf

September 15, 2016

https://github.com/sgraf812/hal16

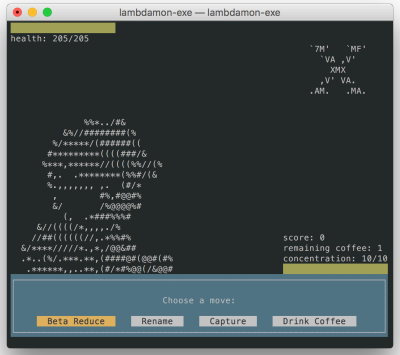
Motivation

Problem Description

$$(\lambda x.xx)(\lambda x.xx)$$

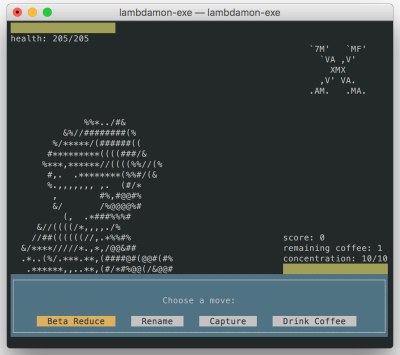
[1] [2]

Plugin Architecture Requirements



Plugin Architecture Requirements

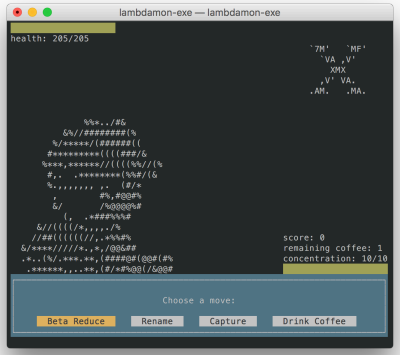
Extensibility through third party code



Plugin Architecture Requirements

Extensibility through third party code

Haskell as extension language

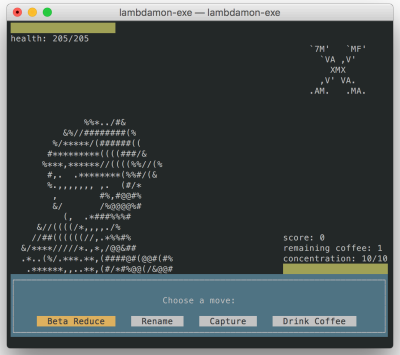


Plugin Architecture Requirements

Extensibility through third party code

Haskell as extension language

Stand-alone No compiler toolchain should be required on the client



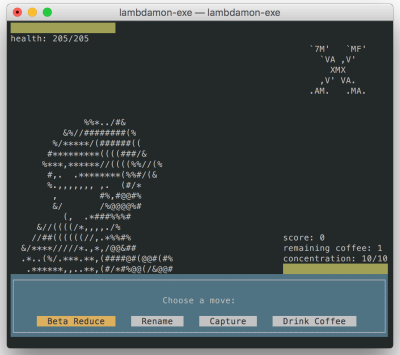
Plugin Architecture Requirements

Extensibility through third party code

Haskell as extension language

Stand-alone No compiler toolchain should be required on the client

Type safety Early and graceful recognition of incompatible extensions



Plugin Architecture Requirements

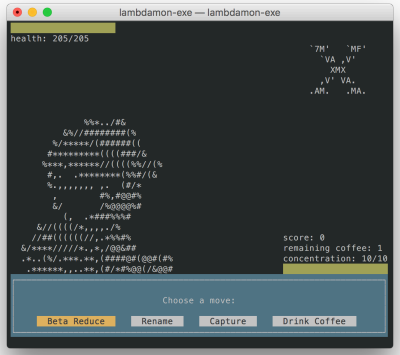
Extensibility through third party code

Haskell as extension language

Stand-alone No compiler toolchain should be required on the client

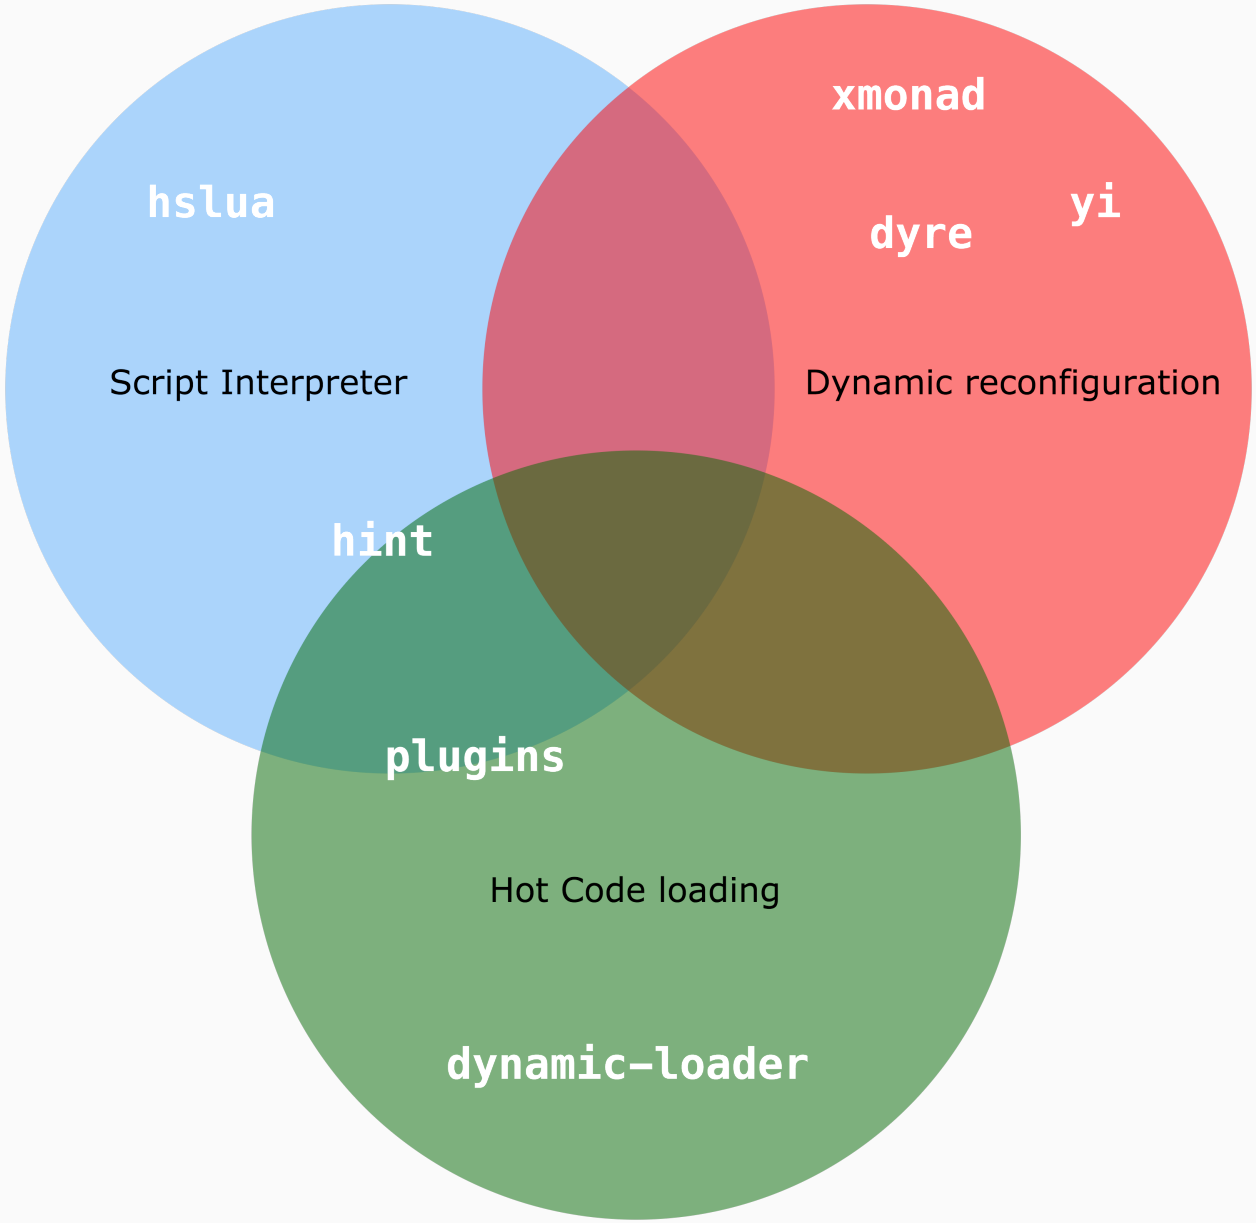
Type safety Early and graceful recognition of incompatible extensions

Maturity Easy integration in a `Cabal` build process



Shootout

Contenders



hslua
Script Interpreter
xmonad
dyre
yi
Dynamic reconfiguration
hint
plugins
Hot Code loading
dynamic-loader

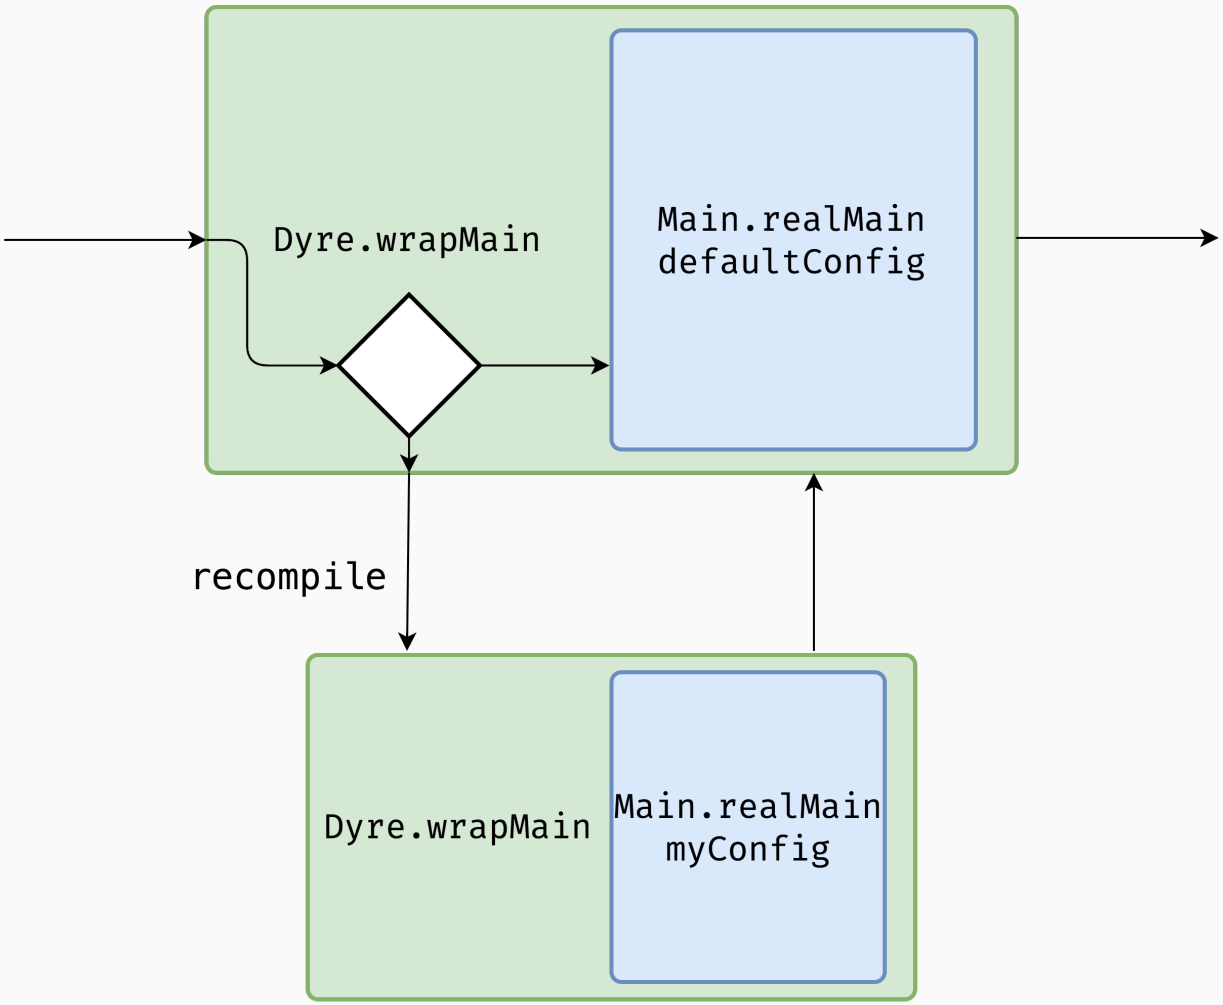
hslua

Extensibility	can't be easier for third parties, see WoW. ✓✓
Haskell	is not lua. ✗
Stand-alone	The C bits are statically linked, no further dependencies. ✓✓
Type safety	Neither in called code nor at API boundaries, also lua stack. ✗✗
Maturity	lua is battle-tested and dead simple to include, yet `hslua`'s API is rather low-level. ✓

`hint`

Extensibility	Just drop in source files, although package dependencies are resolved through GHC package registry ✓
Haskell	✓
Stand-alone	Uses the GHC API, including compilation specific settings paths ✗
Type safety	through broken `Typeable` overloads, falling back to `read`/`show` serialization. ✗
Maturity	Most-used (52 reverse deps) contender according to hackage. ✓

dyre



```
Dyre.wrapMain :: (Config -> IO ()) -> IO ()
Main.realMain :: Config -> IO ()
```

dyre

Extensibility	You can't have more than one config file. Merging them requires knowledge of Haskell. ✗
Haskell	✓
Stand-alone	Needs a complete compiler/stack toolchain available. ✗✗
Type safety	There are no API boundaries, it's all one program and consequently type-checked as one. ✓✓
Maturity	Rotting. Only really works with GHC and the global package registry. Mind-bending API. ✗

dynamic-loader

Extensibility	Just drop in object archives. ✓✓
Haskell	✓
Stand-alone	Although it depends on the GHC API, it works on a fresh installation. ✓
Type safety	Needs reproducible builds in order to work seamlessly. Installed package id needed to find objects. Type errors at API boundaries lead to crashes at runtime. ✗
Maturity	Unwieldy, scarcely documented API. Handling GHC generated symbols is low-level and unresolved. 0 reverse deps. ✗

A word about `plugins`

Extensibility Just drop in object files. Package dependencies via `package.conf`s (outdated) ✓✓

Haskell ✓

Maturity Nicer API than `dynamic-loader`, but it's horribly outdated and broken. ✗✗✗

Summary

	`hslua`	`hint`	`dyre`	`dynamic-loader`	`plugins`
Extensibility	✓✓	✓	✗	✓✓	✓✓
Haskell	✗	✓	✓	✓	✓
Stand-alone	✓✓	✗	✗✗	✓	?
Type safety	✗✗	✗	✓✓	✗	?
Maturity	✓	✓	✗✗	✗	broken

Thanks! Questions?
